ubuntu@ip-172-31-10-190:~$ #LabName:53.CheckingSystemUptime
ubuntu@ip-172-31-10-190:~$ #Objectives
ubuntu@ip-172-31-10-190:~$ #Understand how to determine the uptime of a system using command line
tools.Learn to interpret and analyze system load averages.
ubuntu@ip-172-31-10-190:~$ #Task 1: Use the uptime Command to Check System Uptime
ubuntu@ip-172-31-10-190:~$ uptime
 04:25:02 up 6 min,  3 users,  load average: 0.10, 0.22, 0.13
ubuntu@ip-172-31-10-190:~$ #The uptime command displays the current time, how long the system has been
running, the number of users currently logged in, and the system load averages for the past 1, 5, and 15 minutes.
ubuntu@ip-172-31-10-190:~$ uptime
 04:25:31 up 6 min,  3 users,  load average: 0.06, 0.20, 0.13
ubuntu@ip-172-31-10-190:~$ #Current Time: The system's current local time.
ubuntu@ip-172-31-10-190:~$ #Uptime: Shows the total time the system has been running. In the example, the
system has been running for 10 days and 22 hours.
ubuntu@ip-172-31-10-190:~$ #Number of Users: Indicates how many users are logged onto the system.
ubuntu@ip-172-31-10-190:~$ #Load Average: Represents the number of processes that are actively demanding
CPU time.
ubuntu@ip-172-31-10-190:~$ ^C
ubuntu@ip-172-31-10-190:~$ #04:25:31. Current system time (local time on the server).
ubuntu@ip-172-31-10-190:~$ #up 6 min: The system has been running for only 6 minutes. This is a very fresh
boot/reboot.
Implication: The system is still in its early stabilization phase. Many background services are still starting, caches
are cold, and initial processes (like logging, monitoring agents, Docker containers, etc.) may still be launching
-bash: syntax error near unexpected token `('
ubuntu@ip-172-31-10-190:~$ #3users:One administrator with multiple sessions (SSH + local terminal +
screen/tmux).Multiple users logged in simultaneously.Automated processes or monitoring tools counting as users.
ubuntu@ip-172-31-10-190:~$ #Performance Evaluation
ubuntu@ip-172-31-10-190:~$ #Very healthy system state. Load averages this low (well below 1.0) indicate the
system is almost completely idle.
ubuntu@ip-172-31-10-190:~$ #On modern systems (even single-core), a load average under 0.7–1.0 is generally
considered comfortable.Here the 1-minute load is only 0.06 — meaning the CPU is sitting idle nearly all the
time.The slight rise in the 5-minute average (0.20) compared to 1-minute (0.06) suggests there was a small burst of
activity a few minutes ago (possibly during boot or service initialization), which is now subsiding.
ubuntu@ip-172-31-10-190:~$ #With only 6 minutes of uptime, this reading is not yet fully representative of normal
workload behavior. Load averages become more meaningful after several hours of operation
ubuntu@ip-172-31-10-190:~$
ubuntu@ip-172-31-10-190:~$ #Conclusion: In this lab,I learned how to use the uptime command to assess system
uptime and load averages.I understood how to interpret basic system performance metrics, including the
implications of different load average values.These skills are fundamental for maintaining system health and
efficiency in production environments.
ubuntu@ip-172-31-10-190:~$
